

a, paired Δ per complex, mean over k = 3 folds; complex-clustered bootstrap, 5,000 replicates, seed 20260803. Composite = z-mean of (ipTM, -interface pAE, interface pLDDT) z-scored WITHIN each run (n = 117 / 58 / 58). The 60 Boltz-2 and the 60 reverse-direction complexes are the SAME set, nested in the 120; on those 60, AF2 / steer-ProteinMPNN gives +0.226 (70% of its span), so the AF2 / Boltz-2 difference is not a complex-set effect. b, judge-leverage = the per-complex mean L over the sampled interface residues; method dumped3, same bootstrap.
