

a confidence reads one coordinate of P; leverage reads the whole P → Q move

example position: 3SZK chain C F44 (a hotspot) · bars are the real 20-simplex

diffusion $\varepsilon_{\theta}(x | c)$ — classifier-free guidance is this same difference
 this work $\log p(\cdot | X_{\text{complex}})$ — $\log p(\cdot | X_{\text{monomer}})$

b confidence does not pin leverage down

13,401 positions · 343 complexes · 327 hotspots

c and neither does all of P

GBM / random forest, complex-held-out

d steer with it, an independent model agrees

frozen ProteinMPNN, scored by ESM-IF1 · $n=271$

e at no cost to native recovery

the L direction is native-consistent too
