

confidence is lost at the interface, not in the fold

ILLUSTRATIVE · 1GL0_E_I, the pre-registered median-effect complex · one fold per arm, not best-of-k

C α trace of the AF2-multimer rank-1 model, coloured by the pLDDT ColabFold wrote to the B-factor column; the larger marks are the 43 interface positions that the annotated interface pLDDT averages over. Each arm is the fold whose ipTM is closest to that arm's mean — representative, not best-of-k. The three are superimposed on the wt receptor chain (C α RMSD 0.57 and 0.71 Å for L and random: they differ in confidence, not in pose) and projected on ONE basis, PC1–PC2 of the wt C α cloud. The effect size is the cohort statistic, not this picture: arm-mean ipTM 0.907 (L) vs 0.710 (random) here, Δ 0.197, against a median Δ of 0.183 over 60 complexes.
